

Calculation Cover Sheet

Client: **Columbia Water**

Project: **30" Force Main Relocation Under I-20**

Project No: 10207730-20.2

Rev: 1

Calculation No: Type Calc No. here

Page: #. of #.

Title: **Structural Design – TA10**

Purpose: Structural design of the end thrust restraint for the 30" pipe, for 150 psi (total). Thrust restraint sized based upon DIPRA Thrust Restraint Design Guide.

Originator: M. Eric Martin

Date: 8/13/22

Design Pipe Thrust Block

- Design in-line thrust Restraint for 30" pipe for worst Case Dead-End.

- Pipe: 30" ϕ

$$\text{Area internal} = \frac{\pi}{4}(30)^2 = 707 \text{ in}^2$$

- Pressure: 50 psi (operating)

100 psi (Surge)

150 psi

$$* \text{ Total Thrust} = \frac{150(707)}{1000}$$

$$= 106 \text{ k}$$

* Use DIPRA Thrust Restraint Design Guide to Design Thrust Block

- US Safety Factor of 1.5

- From Boring, most Soil in upper areas is Silt

- Use 1500 psf for Allowable Bearing
(See DIPRA)

$$\text{Area Bearing} = \frac{SF(T)}{S_b} = \frac{1.5(106 \text{ k})(1000 \frac{\text{lb}}{\text{k}})}{1500 \text{ psf}}$$

$$= 106 \text{ SF}$$

The following are general criteria for bearing block design.

- Bearing surface should, where possible, be placed against undisturbed soil. Where it is not possible, the fill between the bearing surface and undisturbed soil must be compacted to at least 90% Standard Proctor density.
- Block height (h) should be equal to or less than one-half the total depth to the bottom of the block, (H_t), but not less than the pipe diameter (D').
- Block height (h) should be chosen such that the calculated block width (b) varies between one and two times the height.

TABLE 1
Horizontal Bearing Strengths

| Soil | *Bearing Strength S_b (lb/ft ²) |
|------------|--|
| Muck | 0 |
| Soft Clay | 1,000 |
| Silt | 1,500 |
| Sandy Silt | 3,000 |
| Sand | 4,000 |
| Sandy Clay | 6,000 |
| Hard Clay | 9,000 |

*Although the above bearing strength values have been used successfully in the design of thrust blocks and are considered to be conservative, their accuracy is totally dependent on accurate soil identification and evaluation. The ultimate responsibility for selecting the proper bearing strength of a particular soil type must rest with the design engineer.

The required bearing block area is

$$A_b = hb = \frac{S_f T}{S_b}$$

Then, for a horizontal bend,

$$b = \frac{S_f 2 PA \sin (\phi/2)}{h S_b}$$

where S_f is a safety factor (usually 1.5 for thrust block design). A similar approach may be used to design bearing blocks to resist the thrust forces at tees, dead ends, etc. Typical values for conservative horizontal bearing strengths of various soil types are listed in Table 1.

In lieu of the values for soil bearing strength shown in Table 1, a designer might choose to use calculated Rankine passive pressure (P_p) or other determination of soil bearing strength based on actual soil properties.

Gravity thrust blocks may be used to resist thrust at vertical down bends. In a gravity block, the weight of the block is the force providing equilibrium with the thrust force. The design problem is then to calculate the required volume of the thrust block of a known density. The vertical component of the thrust force in Figure 6 on page 8 is balanced by the weight of the block.

It can easily be shown that $T_y = PA \sin \phi$. Then the required volume of the block is

$$V_g = \frac{S_f PA \sin \phi}{W_m}$$

where W_m = density of the block material. Here, the horizontal component of the thrust force

$$T_x = PA (1 - \cos \phi)$$

must be resisted by the bearing of the right side of the block against the soil. Analysis of this aspect will follow like the above section on bearing blocks.

Calculations of V_g and T_x for orientations other than when one leg is horizontal should reflect that specific geometry.
